

Project acronym:	ACAT
Project Type:	STREP
Project Title:	Learning and Execution of Action Categories
Contract Number:	600578
Starting Date:	01-03-2013
Ending Date:	28-02-2016

Deliverable number:	D6.1
Deliverable Title:	Web site
Type (Internal, Restricted, Public):	PU
Authors:	M.Tamosiunaite, F. Wörgötter
Contributing Partners:	UGOE

Contractual Date of Delivery to the EC: 31-05-2013
Actual Date of Delivery to the EC: 31-05-2013

Web site.....	2

Executive summary

The deliverable introduces the web site of the ACAT project.

Project web site

The deliverable introduces the ACAT project web site. It has been launched in April, 2013 and can be found under the address:

www.acat-project.eu

The web-page introduces the focuses of the project (menu item "Home"), news, publications, partners and contacts (see Fig. 1,2).

The internal area of the project is in the process of preparation and will result in SVN repository for exchange of material between project partners.

ACat Project

ACAT focuses on how artificial systems (robots) can understand and utilize information made for humans.

Everyday we (humans) are using many sources of information, for example books, videos, the Internet, etc., from which we extract information also about new tasks. For example, if you have never tried a punctured bicycle tire before, you can access wikiHow ([How-a-Puncture-in-a-Bike-Tire](#)) to learn how to do this.

Any of these information sources, however, is usually incomplete and leaves out all information "that goes without saying". What does that mean? For example, if a text source tells you to use a hammer for a certain task it will usually not tell you how to hold the hammer (by the handle, not by the tool end), how to wield it (usually hitting with the flat part of the tool end – but there are exceptions to this), let alone how to shape the dynamics of your movement (making a smooth swing). Usually all of this is learned by us during childhood and if a robot will – some times painfully – find out that a presumably good manual, textbook, Internet page, cannot be used, because of some gap of information.

This, for many skills, humans take internalized and stored a lot of readily available information and our external textual or pictorial sources rarely assist us in this and do not reflect "the obvious".

The goal of the ACAT project is to provide machines (robots) with this type of tacit information and to generate internal knowledge about individual tasks by way of creating and storing all required action information into so-called "Action Categories".

To achieve this, ACAT generates a dynamic process memory by extracting and storage of action categories from large bodies of human compatible sources (text, images). Action categories are designed to include the actual action-executing bit into a large amount of context information ("background"). They are obtained by combining linguistic analysis with grounded exploration and action simulation.

To make them available to a wide variety of robots ACAT will structure and store the action categories in an action-specific knowledge base.

The ACAT system then uses action-categories to compile robot-executable plans. Execution benefits strongly from the rich context information present in the action-categories because this allows for generalization (for example replacement of objects in an action). It also permits us to specifically address ambiguity, incompleteness and uncertainty in planning.

The ultimate purpose of ACAT is to equip the robot – on an ongoing basis – with abstract, functional knowledge, normally made for humans, about relations between actions and objects leading to a system which can act intelligently.

As Industrially relevant scenario, ACAT uses "instruction sheets" (manuals), made for human workers, and translates these into a robot-executable format. This way the robot will be able to partially take over human tasks without time-consuming programming procedures.

Similar to computer science, where the development of the first compilers had led to a major step forward, the main impact of this project is that ACAT develops a robot-compiler, which translates human understandable information into a robot-executable program.

Fig. 1. Screen-shot of the web-page "Home" area.

The screenshot shows the 'News' section of the ACat project website. At the top left is the ACAT logo featuring a black cat silhouette. The title 'ACat' is prominently displayed, followed by the subtitle 'Capturing human knowledge in Action Categories'. Below the title are three small images: a robot arm, a diagram of action categories, and another robot arm. A navigation bar at the top includes links for Home, News, Publications, Partners, Internal Area, and Contact us. The main content area starts with a heading 'News' and a sub-heading 'Göttingen Symposium on The Semantics of Action' dated June 10-11 2013. It contains text about the symposium and links to abstracts and a PDF program. Below this is a section titled 'Website First Version' dated Monday, 29 April 2013, with a note that it's a first version published in April 2013. At the bottom are copyright information, a European Union flag, and a link to the FP7 home page.
